Mindanao River Basin

1 Introduction

The Mindanao River Basin is one of the selected pilot basins for Rapid Water Accounting. It covers an area of 21,503 km² (between 124°6'E 6°3'N and 125°27'E 8°33'N), see Figure 1.

The catchment contains the area from the mountains of Impasug-ong in Bukidnon (known as Upper Pulangi River), Kabacan River (relabelled as Mindanao River), Lower Pulangi River and Ligawasan Marsh.

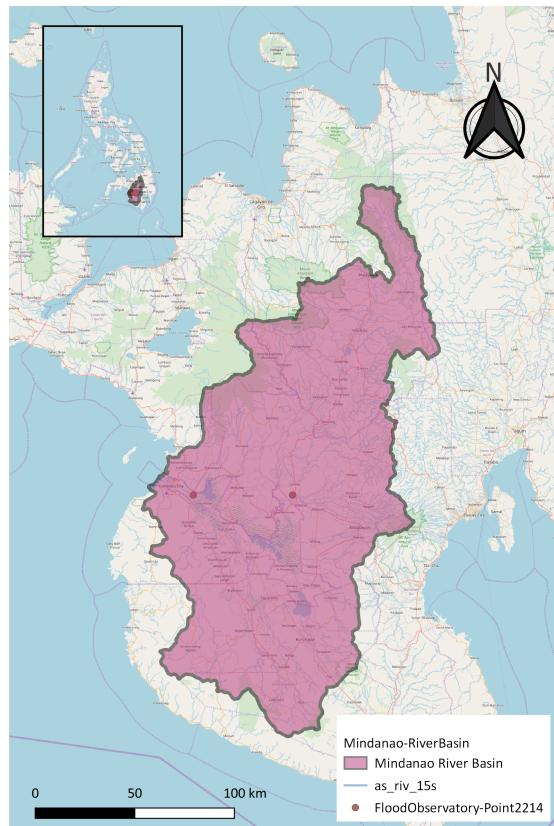

Figure 1: Mindanao River Basin

1.1 Observation data

Discharge is collected from Flood Observatory. Two flooding periods can be found, which happened in 2008 and 2011, see Figure 2.

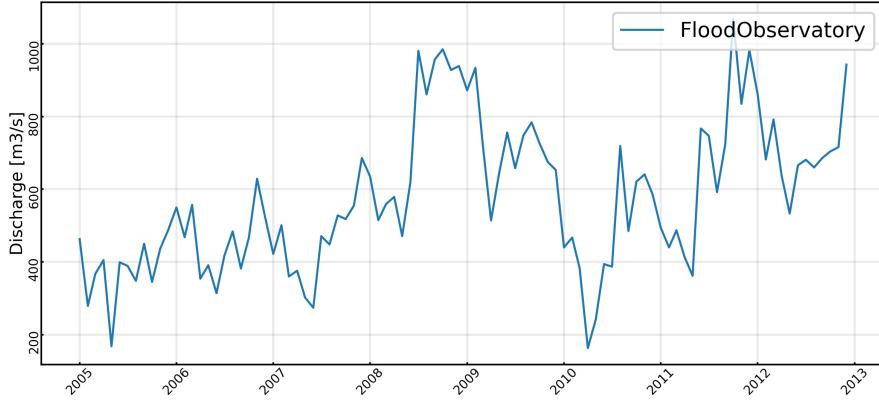

Figure 2: Discharge at river mouth of Mindanao River

2 RS data analysis

The purpose of this study is to select remote sensing products for water accounting, by evaluating the performance of water balance analysis. Three evaluation criteria are applied in the study, Pearson correlation coefficient (PCC), coefficient of determination (R²) and root mean square error (RMSE). PCC - The covariance of the two variables divided by the product of their standard deviations. It has a value between +1 and -1, where 1 is total positive linear correlation, 0 is no linear correlation, and -1 is total negative linear correlation.

R² - The proportion of the variance in the dependent variable that is predictable from the independent variable(s). Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

RMSE - The standard deviation of the residuals (prediction errors). It is a measure of how spread out these residuals are. In other words, it tells you how concentrated the data is around the line of best fit.

2.1 Review of RS products

To evaluate remote sensing products for water balance analysis, three precipitation products, five evapotranspiration products and three GRACE solutions are collected, see Table 1. After download products, all data was clipped to Mindanao River Basin. Then the datasets were resampled to spatial resolution of 0.05 degree and aggregated to monthly and yearly time series. The detail description of each product can be found in Annex 1.

Table 1: Remote sensing products

Product	Type	Duration	Temporal Res.	Spatial Res.
ALEXI	Evapotranspiration	2005 - 2012	daily	0.05°
CMRSET	Evapotranspiration	2005 - 2012	monthly	0.05°
GLEAM	Evapotranspiration	2005 - 2012	monthly	0.25°
MOD16A2	Evapotranspiration	2005 - 2012	eight-daily	463m
SSEBop	Evapotranspiration	2005 - 2012	monthly	1km
CHIRPS	Precipitation	2005 - 2012	monthly	0.05°
GPM	Precipitation	2005 - 2012	monthly	0.1°
TRMM	Precipitation	2005 - 2012	monthly	0.25°

Mindanao River Basin

Product	Type	Duration	Temporal Res.	Spatial Res.
CSR	GRACE	2005 - 2012	quasi-monthly	1°
GFZ	GRACE	2005 - 2012	quasi-monthly	1°
JPL	GRACE	2005 - 2012	quasi-monthly	1°

2.1.1 Precipitation products

The precipitation products present similar pattern. Figure 3 shows the time series plots of precipitation from the three products. There is no missing values from 2005 to 2013. CHIRPS has the higher precipitation in the summer.

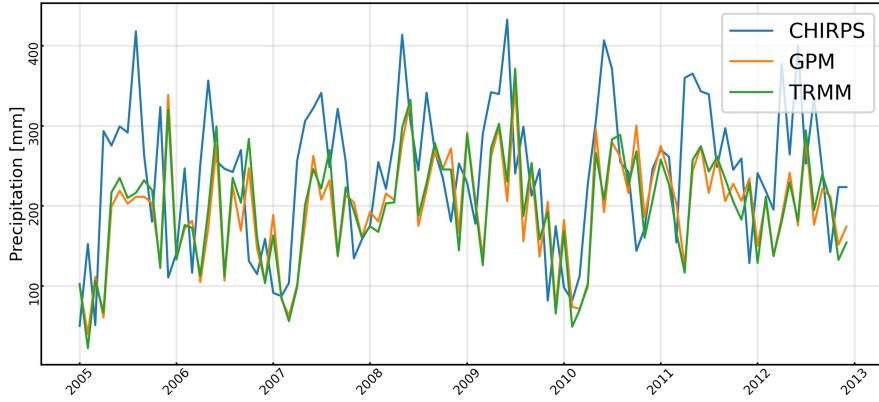

Figure 3: Precipitation products for Mindanao River Basin

Figure 4 shows the correlation between the products. TRMM and GPM obtained the highest correlation with PCC of 0.97, while CHIRPS versus GPM had the lowest PCC of 0.29.

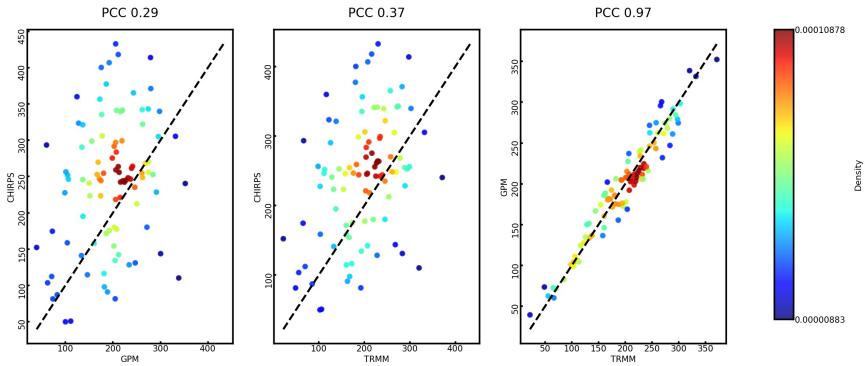

Figure 4: Correlation between precipitation products (unit: mm/month)

The monthly mean and annual precipitation from the products are illustrated in the Figure 5 and Fig-

Mindanao River Basin

ure 6. CHIRPS had highest values in wet season while TRMM shows lowest values in dry months. GPM values were largely between CHIRPS and TRMM in most of the months. The annual precipitation values do not show significant differences either among the different products except for 2012 when CHIRPS showed a significant higher value compared to the other products (up to 85 mm/year)

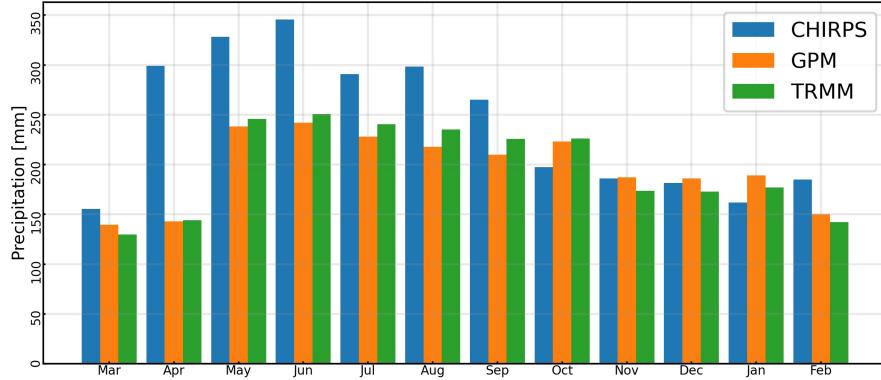

Figure 5: Monthly mean precipitation for Mindanao River Basin

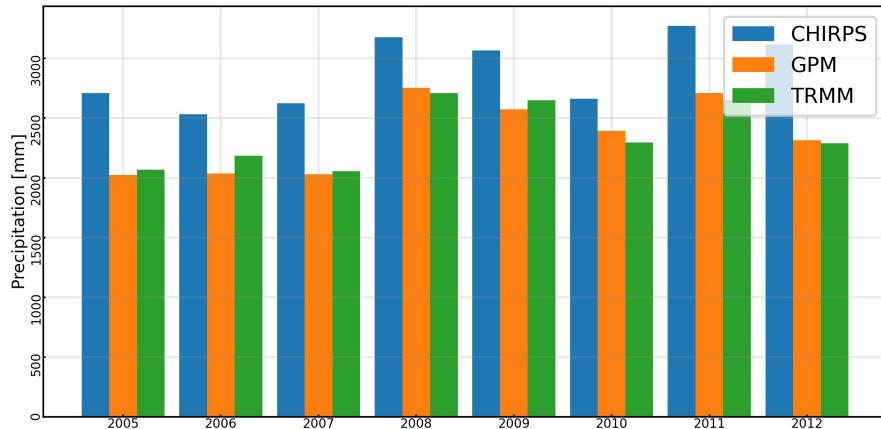

Figure 6: Annual precipitation for Mindanao River Basin

2.1.2 Evapotranspiration products

The evapotranspiration products have similar pattern. Figure 7 shows the time series plots of precipitation from the five products. CHIRPS has the higher precipitation in the summer.

Mindanao River Basin

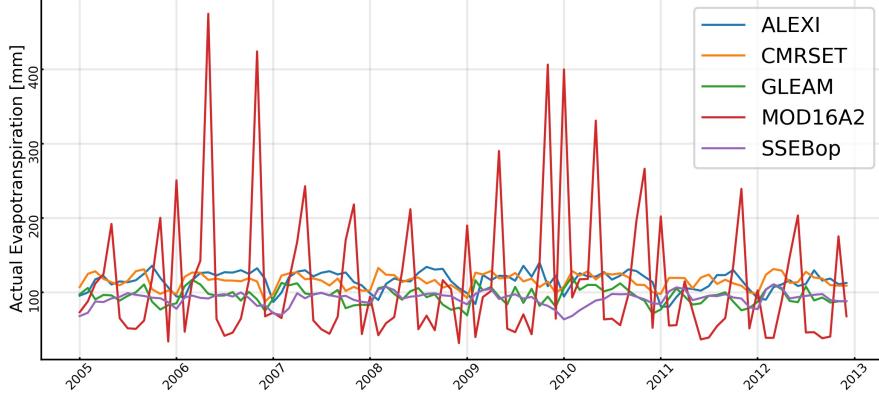

Figure 7: Annual evapotranspiration for Mindanao River Basin

In terms of correlation, CMRSET and GLEAM showed the highest correlation with PCC of 0.82, while SSEBop versus MOD16A2 had the lowest PCC of -0.3, see Figure 8.

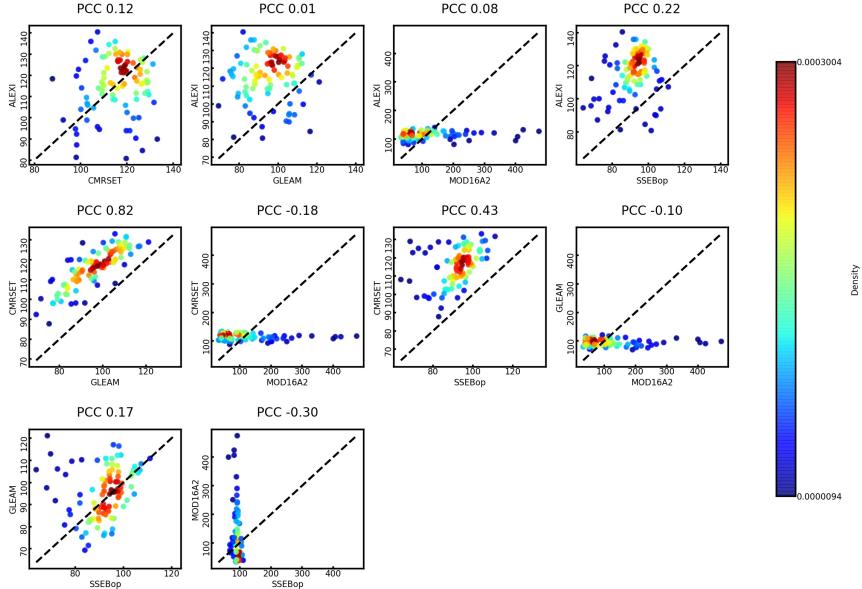

Figure 8: Correlation between actual evapotranspiration products (unit: mm/month)

The monthly mean and annual actual evapotranspiration from the products are plotted in the Figure 9 and Figure 10. The highest values in wet season was occurred in MOD16A2 while MOD16A2 presented highest values in dry months. GLEAM values were largely between MOD16A2 and CMRSET in most of the months.

The annual actual evapotranspiration values do not show significant differences either among the dif-

Mindanao River Basin

ferent products except for 2010 when MOD16A2 showed a significant higher value compared to the other products (up to 800mm/year)

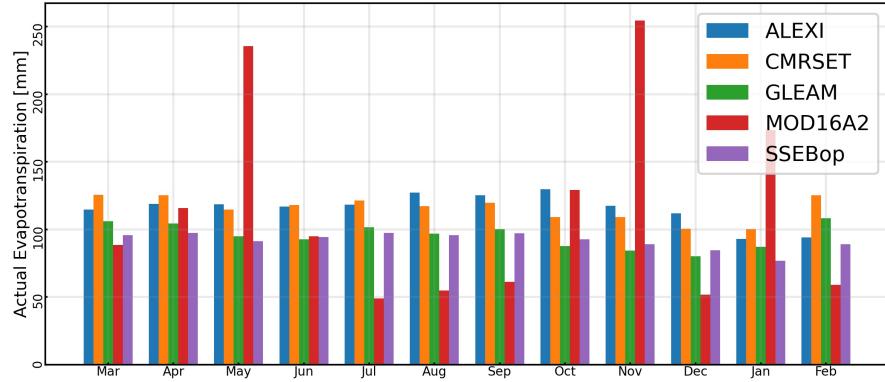

Figure 9: Monthly mean actual evapotranspiration for Mindanao River Basin

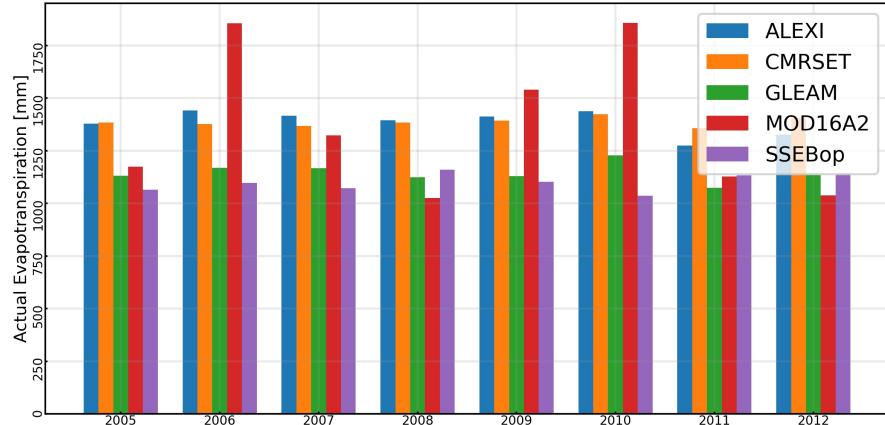

Figure 10: Annual actual evapotranspiration for Mindanao River Basin

2.1.3 Grace solutions (change in storage)

The GRACE products show similar pattern. Figure 11 is the time series plots of precipitation from the three products. CSR estimates larger dynamic of storage change compare with other products.

Mindanao River Basin

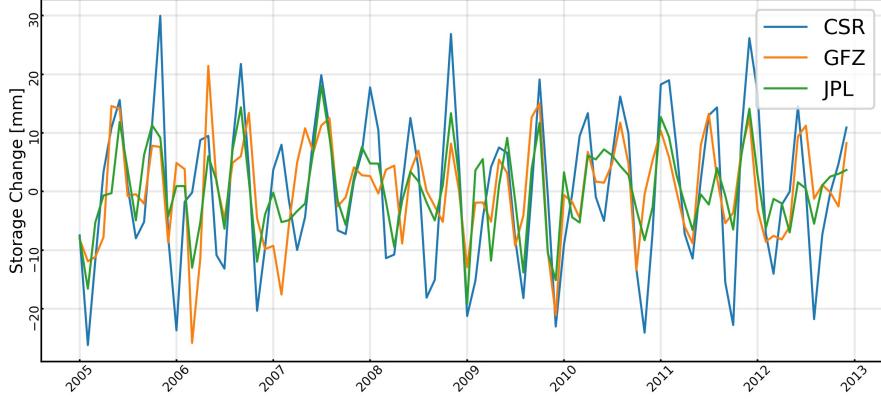

Figure 11: GRACE products for Mindanao River Basin

In terms of correlation, CMRSET and GLEAM showed the correlation with PCC of 0.82, which means the products are relatively correlated, see Figure 12.

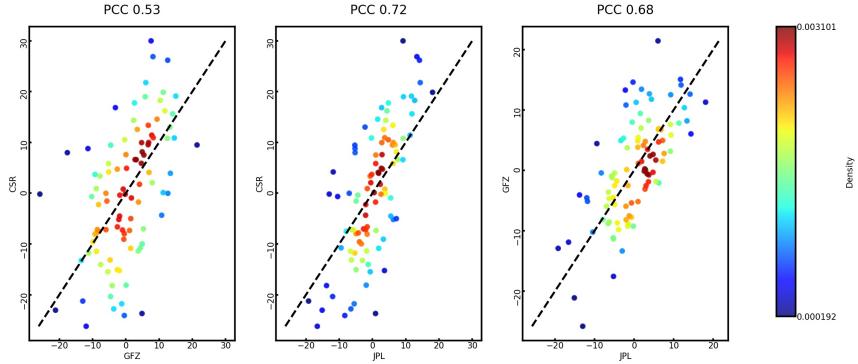

Figure 12: Correlation between GRACE products (unit: mm/month)

The monthly mean and annual storage change from the products are illustrated in the Figure 13 and Figure 14. GFZ solution produced larger volume of storage gain in wet season, CMRSETlost less storage in dry months.

Mindanao River Basin

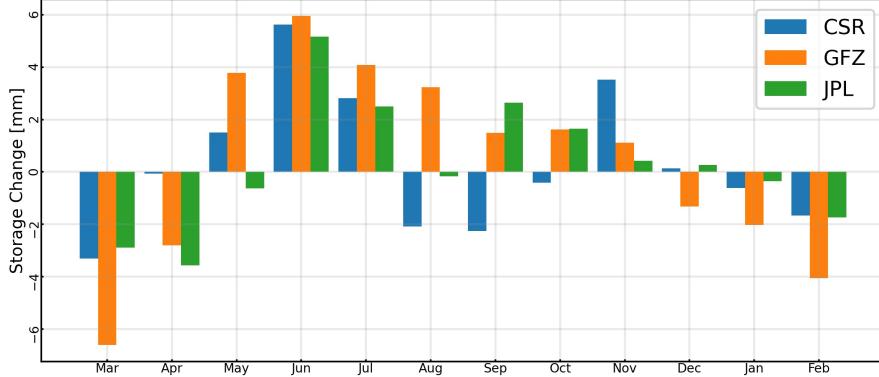

Figure 13: Monthly mean storage change for Mindanao River Basin

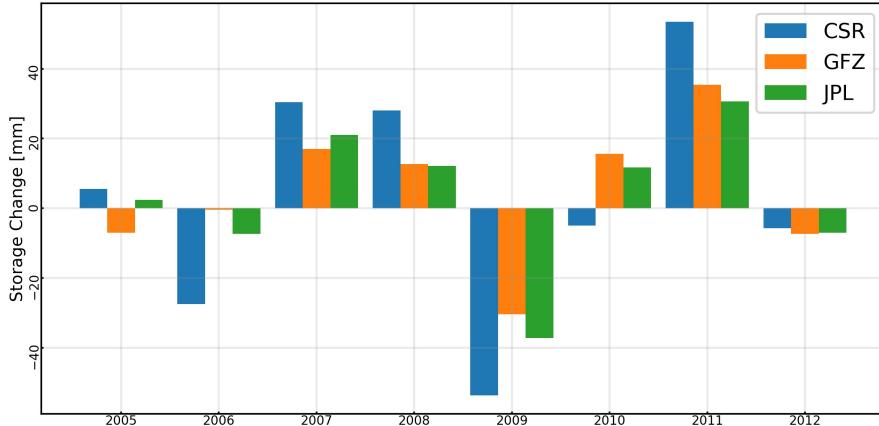

Figure 14: Annual storage change for Mindanao River Basin

2.2 Runoff comparison

Total 60 different possible combinations to compute the water balance for Mindanao River Basin from three precipitation, five evapotranspiration and three GRACE solutions, see Figure 15.

- PCC values vary from -0.04 to 0.29. The best performing combination in terms of PCC is GLEAM for evapotranspiration, GPM for precipitation and CSR for change in storage. The second best combination is GLEAM, GPM and GFZ with PCC of 0.26....
- R2 values are in the range from -0.90 to 0.06. The best performing combination in terms of R2 is MOD16A2 for evapotranspiration, GPM for precipitation and CSR for change in storage. The second best combination is CMRSET, GPM and CSR with PCC of 0.05....
- The minimum RMSE value is 64.44. The best performing combination in terms of RMSE is CMRSET for evapotranspiration, GPM for precipitation and GFZ for change in storage. The second best combination is CMRSET, GPM and JPL with PCC of 64.72....

Mindanao River Basin

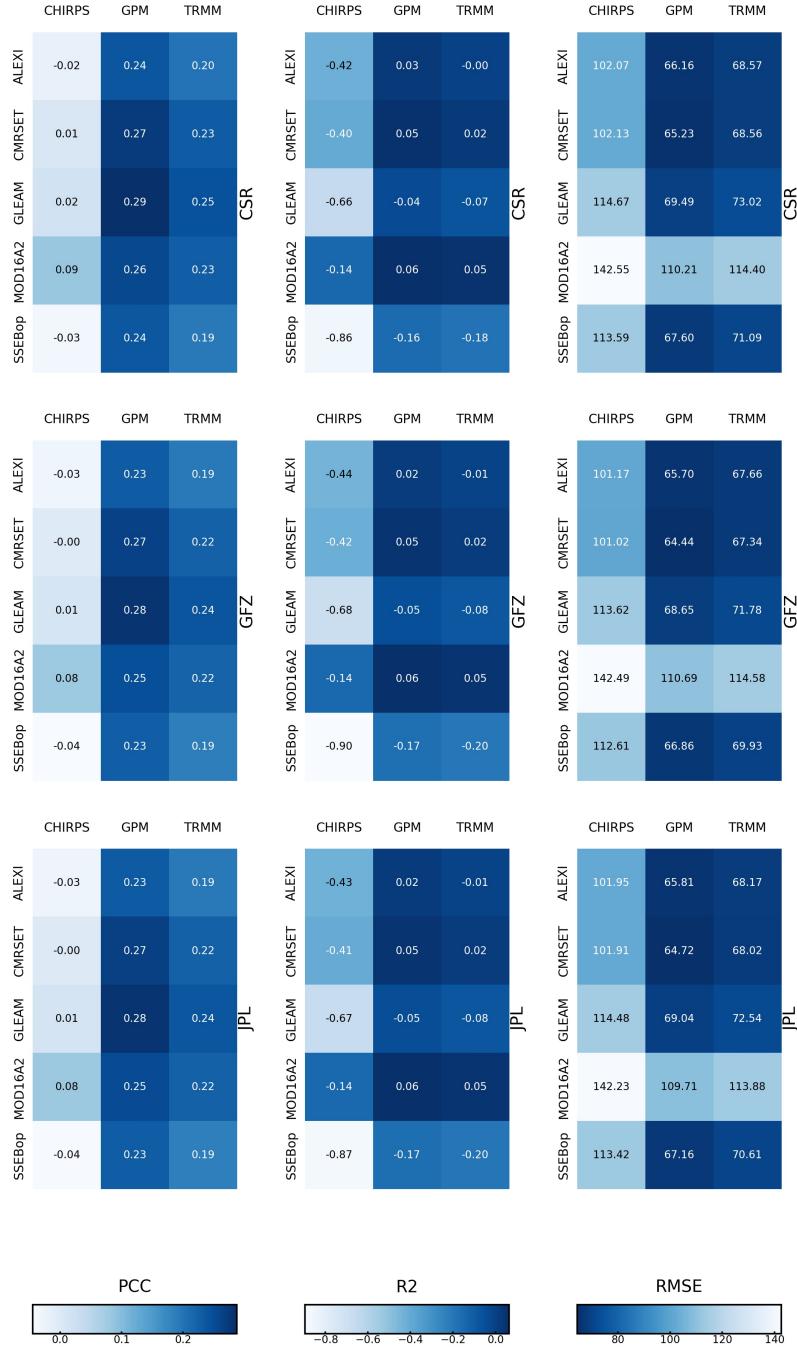

Figure 15: Performance of different combinations of the remote sensing products to calculate the runoff generated

2.3 Water Balance error

Water balance error is the difference between $P - ET - \Delta S$ and runoff. Figure 16 shows the yearly mean water balance error. The combination GPM and MOD16A2 has the lowest error ranging around 1.35%. However GPM, CMRSET and GFZ has the lowest absolute error $584.81 \text{ Mm}^3/\text{year}$, see Annex 2, Annex 3. The runoff maps of these two are plotted in Figure 17.

Mindanao River Basin

Figure 16: Water Balance error

Mindanao River Basin

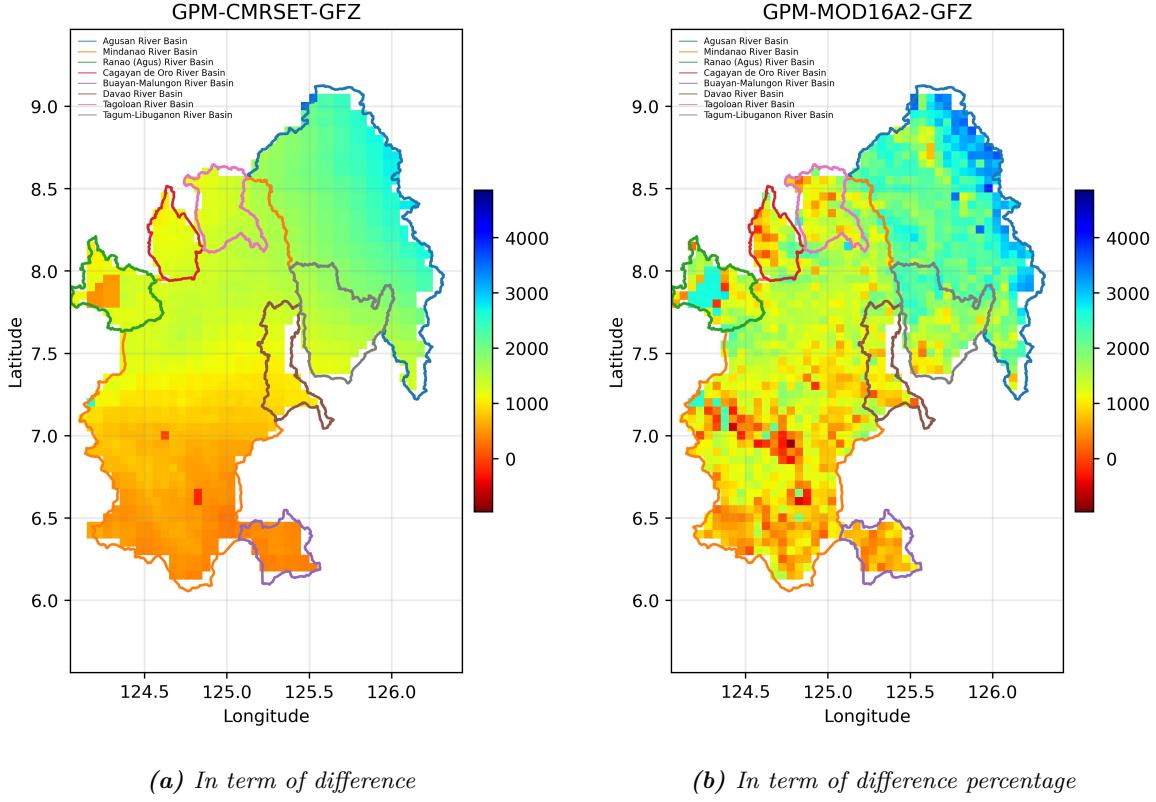

Figure 17: Yearly mean runoff generation map of the best combination

3 Selection of RS products for WA

Due to the PCC and R² scores are not large enough, which means the correlation is not significant between water balance calculated by different combination and runoff. RMSE is considered as the first criteria to select the best combination of remote sensing products in this study.

Thus, precipitation product GPM, evapotranspiration product CMRSET and GRACE solution GFZ are selected for further analysis.

Without the full information on other basin transfers, the water balance $P - ET - \Delta S$ is considered in reasonable agreement with outflow. The precipitation is 3% lower than the water balance. The average $P - ET - \Delta S$ is 585 $Mm^3/year$ higher than the sum of flow at outlet. The largest difference is found in the year 2012, which might be attributed to other unaccounted transfers, see Table 2.

Table 2: The annual $P - ET - \Delta S$ and Q , (unit: $Mm^3/year$)

Year	P	ET	ΔS	$P - ET - \Delta S$	Q	Diff	%Diff

Annex 1 Remote sensing products

Precipitation

CHIRPS – The Climate Hazards group Infrared Precipitation with Stations (CHIRPS) dataset, developed by the U.S. Geological Survey Earth Resources Observation and Science Center and Santa Barbara Climate Hazards Group at the University of California is precipitation product based on multiple data sources (Funk et al., 2015). CHIRPS incorporates monthly precipitation climatology (Climate Hazards Group Precipitation Climatology, CHPClim), quasi-global geostationary thermal infrared satellite observations, TRMM product, atmospheric model precipitation fields from the National Oceanic and Atmospheric Administration (NOAA) Climate Forecast System (CFS), and observed precipitation (Funk et al., 2015).

TRMM – The Tropical Rainfall Measuring Mission (TRMM), a joint mission of NASA and the Japan Aerospace Exploration Agency, was launched in 1997 to study rainfall for weather and climate research. TRMM Multi-satellite Precipitation Analysis (TMPA) algorithm merges a variety of existing ground- and satellite-based observations to yield high spatial () and temporal resolution (three-hourly instantaneous retrievals) observations with a higher degree of accuracy (Huffman et al., 2007).

GPM - NASA/JAXA Global precipitation measurement (GPM) mission in coordination with the Goddard Earth Sciences Data and Information Services Center (GES DISC) is the Integrated Multi-satellite Retrievals for GPM, which merges precipitation estimates from passive microwave (PMW), calibrated infrared (IR) sensors and monthly surface precipitation gauge analysis data to provide half-hourly precipitation estimates on a grid over the N-S domain. GPM extend the spatial coverage from its predecessor (TRMM), and also provide improved measurements of precipitation globally (Liu et al., 2017).

Evapotranspiration

ALEXI - Is a coupled two source land surface one dimensional atmospheric boundary layer (ABL) model. The lower boundary conditions for the two source model are provided by thermal IR observations taken at two times during the morning hours. The ABL model then relates the rise in air temperature above the canopy and the growth of the ABL to the time integrated influx of sensible heating from the surface. (Anderson et al., 2007).

CMRSET - CSIRO MODIS Reflectance-based Evapotranspiration (Guerschman et al., 2009).

GLEAM - A set of algorithms that separately estimate the different components of land evaporation (or “evapotranspiration”): transpiration, bare-soil evaporation, interception loss, open-water evaporation and sublimation. Additionally, GLEAM provides surface and root-zone soil moisture, potential evaporation and evaporative stress conditions. (Miralles et al., 2011).

MOD16A2 - Based on surface reflectance from MODIS-Terra and interpolated climate data. The algorithm uses monthly values of the Enhanced Vegetation Index (EVI) and the Global Vegetation Moisture Index (GVMI) derived from the MODIS nadir bidirectional reflectance distribution function – adjusted reflectance product (MOD43B4) to scale Priestley-Taylor potential evapotranspiration derived from the climate surfaces. (Mu et al., 2011).

SSEBop - Operational Simplified Surface Energy Balance (Senay et al., 2013).

GRACE Solution

CSR - Center for Space Research at University of Texas, Austin.

GFZ - GeoforschungsZentrum Potsdam

JPL - Jet Propulsion Laboratory processing centers (Swenson and Wahr, 2006; Landerer and Swenson, 2012; Swenson, 2012).
